

Glossary

Animal by-products regulations (ABPR)

UK regulations to control composting and anaerobic digestion of products of animal origin, including food waste containing meat, fish or dairy products. The regulations specify hygiene requirements and treatment standards and are in place to prevent the spread of disease to people and animals.

Contaminants/Contamination

Materials which have not been targeted for collection and should not be present. Contamination can hamper recycling efforts so care is needed to make sure that only the correct, target, items are put out for collection.

Garden waste

Organic or naturally occurring, waste vegetation materials from gardens such as leaves, grass clippings, twigs, etc.

Microbes

Small life forms (usually single cells) which are too small for humans to see but which are essential in nature to break down organic material.

PAS100

A quality standard for compost products. Non-PAS 100 compost can be used on land however, it has to meet set requirements for an exemption.

More details can be found on SEPA's website.

Overview

Open Air Windrow Composting (OAW) uses naturally occurring microbes which feed on organic material (garden waste) and require oxygen. By feeding on the garden waste, the microbes break down the material and turn it into compost. Garden waste is often collected by Councils through kerbside collections (sometimes for part of the year only, between March & November) or at recycling centres.

OAW is not suitable for food waste. This is because the process needed to deal with food waste has to be performed in an enclosed vessel and not in the open air. The Animal By-products regulations control this and were brought in to protect animal and human health. As a result any food waste, even vegetable scrapings from households, cannot be put through OAW.

What goes in?

Garden waste

Organic garden waste materials such as twigs, leaves, grass clippings and prunings are suitable for OAW. Larger items such as branches, tree stumps etc. are too large to fully break down in OAW and should be shredded or cut into smaller pieces first.

What happens?

Material is delivered, sorted to remove incorrect materials (contamination) and shredded.

The shredded materials are piled into long rows known as windrows, in the open air.

Naturally occurring microbes feed on the materials. This creates heat and windrows will often give off steam.

Rows are regularly turned to make sure there is enough oxygen for the microbes to work.

At the end of the process, usually 12-16 weeks, the compost is checked to make sure it meets the necessary quality standard.

What comes out?

Compost: The main product to come out of the process is compost. Provided it meets the required quality standard, known as PAS100, the compost can be used by farmers as a soil conditioner and sold to many markets as long as it is no longer considered to be waste. The compost is often also sold or given away to local residents.

Before being sold, the compost is graded and any contamination removed. Contaminants most commonly include plastics and metals.

The grading also removes any pieces of material which have not completely broken down. This can include items like small tree branches which are often too thick to fully compost. These items are often put back through the process, sometimes after being shredded.

The different grades of compost can be used for different purposes. Some grades are for use as agricultural soil conditioners, others as mulches and others are suitable for landscape gardening or finer grades can be used on golf courses.
